## 1. Introduction

Freedom of association and the effective recognition of the right to collective bargaining are fundamental principles and rights at work. They are the bedrock of sound industrial relations and effective social dialogue. Indicators of trade union representation and collective bargaining coverage can assist in monitoring progress with the realization of these rights. They also provide valuable information on the quality of industrial and employment relations and its role in labour market governance.

The ILO receives frequent requests for statistical information related to trade union membership and collective bargaining from governments, researchers, international organizations and other users. In order to further develop and update statistical indicators of social dialogue, a survey was conducted by the Industrial and Employment Relations Department and the Department of Statistics of the International Labour Office in 2008-09.<sup>1</sup> The aim of the project is threefold: first, to assess the degree to which statistics on trade union density and collective bargaining coverage are available and can be used as an indicator of the strength and quality of social dialogue; second, to use the information to improve the collection and dissemination of such data at both the country and international levels; and third, to provide the ILO with information that might help it develop international guidelines for the collection of these statistics, and so enhance their comparability.

The present note (i) defines the major indicators; (ii) describes the methodology used for collecting the data, and (iii) summarises the main findings of the survey. This Technical Brief is accessible from the web site of the Industrial and Employment Relations Department and will be periodically updated as new materials become available.<sup>2</sup>

## 2. Social dialogue indicators

Social dialogue is defined as all types of negotiation, consultation or simply the exchange of information between representatives of governments, employers and workers on issues of common interest relating to economic and social policy. It covers both tripartite processes and institutions of social dialogue, such as social and economic councils and traditional industrial relations processes and institutions such as trade unions, employers' organizations and collective bargaining.

Autonomous, independent and strong workers' and employers' organizations are critical for effective social dialogue. The quality of that dialogue is determined by the extent to which the social partners are able to negotiate collective agreements that govern terms and conditions of employment and regulate labour relations. The emphasis of this particular inquiry is therefore on primary industrial relations indicators, that is, membership of organizations and the coverage of collective bargaining agreements.

Quantitative data on the membership and density of employers' organizations (measured in terms of both the number of companies and the number of employees) is difficult to collect. With the exception of Europe where the European Industrial Relations Observatory published data on the subject (EIRO, 2004), there is very little available information on employers' organization's membership strength, density and representativeness. Employers' organizations are reluctant to publish membership figures, and often lack data on the number of employees employed by their members (Traxler, 2000). The 2008-09 inquiry thus focussed on the collection of and computation of data on trade union density and collective bargaining coverage.

---

## 2.1 Trade union density

Trade union membership, that is the total number of workers that belong to a trade union, can be an indicator of trade union strength. However, it is important to also have a picture of how significant the level of trade union membership is relative to all those who could join a trade union. What proportion of all those earning a wage belong to a trade union? How do we assess the degree of unionization in highly segmented labour markets where a significant number of workers are counted as own-account workers or work in the informal economy?

Trade union density expresses union membership as a proportion of the eligible workforce and can be used as an indicator of the degree to which workers are organized. However, union density only measures the extent of unionisation and tells us very little about the influence or bargaining power of unions. Collective bargaining may still play a very significant role and collective agreements cover a high proportion of workers in countries with low trade union density, as is the case in France.

## 2.2 Collective bargaining coverage

Collective bargaining is the process through which the social partners arrive at an agreement that regulates both terms and conditions of employment and labour relations. It is important to understand the role that collective bargaining plays in labour market governance. To what degree do collective agreements govern the terms and conditions of all those in employment?

As an indicator of social dialogue, collective bargaining coverage measures the number of workers in employment whose pay and/or conditions of employment is determined by one or more collective agreement(s) as a proportion of all who are eligible to conclude a collective agreement. A collective bargaining coverage rate is an indicator of the degree to which wages and working conditions are regulated by collective agreements. It is a function of the particular features of the industrial relations system. For example, centralized collective bargaining structures tend to be associated with high coverage rates. Coverage rates will also be high in countries which extend the terms of a collective agreement to enterprises and workers who may not be parties to the agreement.

## 3. Methodology for deriving social dialogue indicators

There are no international guidelines for the collection of social dialogue indicators at the country level. The only statistical standard on this issue dates back to October 1926, when the Third International Conference of Labour Statisticians (ILCLS) approved a “Resolution concerning statistics of collective agreements.”<sup>3</sup> This recommended that each country collect information concerning collective agreements including their coverage and contents. While this resolution provides the basis for this inquiry, it is unclear to what extent national statistical agencies and governments follow these guidelines. There is a high degree of methodological variation and data are not comparable. The absence of a methodological basis for comparability is compounded by the fact that industrial relations frameworks differ from country to country. Indicators on trade union density or collective bargaining coverage thus need to be interpreted in the context of the prevailing industrial relations framework and labour market characteristics.

There have been a number of efforts to collect statistics on trade union membership, trade union density and collective bargaining coverage. In 1997 the ILO collected trade union density and collective bargaining coverage estimates for 92 countries. These were published in the ILO World Labour Report (1997/98). However, while widely cited, these estimates were subject to significant methodological difficulties, outlined in the ‘Technical notes’ at the end of the study. Other researchers and organizations have also attempted to collect this information (see databases

---

<sup>3</sup> <http://www.ilo.org/public/english/bureau/stat/download/res/collagr.pdf>

---

in Annex 1). However, they all suffer from similar methodological limitations which mean that the rates are not comparable across countries. The lack of statistical guidelines for collecting these indicators and significant methodological variation also means that data for a particular country differ across these databases.

Following extensive consultations with experts in the area, the ILO launched a pilot project in 2003-04 to collect this information (see Ishikawa and Lawrence, 2005). A questionnaire was sent in two subsequent rounds to 68 countries selected on the likelihood that these countries might collect such data. Whereas the questionnaires were sent to Ministries of Labour, National Statistical Offices, trade unions and employers' organizations in 17 countries in the first round, trade unions and employers' organizations were excluded from the second round (51 countries) as a result of their poor response rate.

The 2008-09 inquiry builds on the methodology and definitions used during the pilot project in 2003-04. It extended the country coverage and significantly improved and simplified the questionnaire. The questionnaire sought to collect sex-disaggregated data on collective bargaining coverage (including by economic sector), bargaining levels, length of collective agreements, information on the extension of collective agreements, trade union membership (including by economic sector) and other information that would assist in harmonizing data. It was sent to the National Statistics Office and Ministries of Labour in over 200 countries and territories. While responses were received from 97 countries, some sent incomplete questionnaires whereas others reported that they did not collect these statistics. Statistical indicators for 64 countries are reported in Tables 1 and 2.

## Comparability of data

The inquiry again revealed significant variation in the methods used to collect the information and the different statistical sources. There was also significant variation in the coverage of the data reported. While many countries reported data for all workers, some countries only reported data for the public sector and others only for the private sector. The coverage of the economic activities also varies to some extent across countries. As a result, data are not directly comparable between countries.

### Sources of statistics on trade union membership and coverage of collective agreements

**Administrative records:** Statistics on trade union membership and coverage of collective agreements can be obtained from the administrative records of trade unions, records maintained by registrars of associations and collective agreements or the registers of other organizations such as bargaining councils. Since this information is collected for administrative purposes, it is imperfect as a source of statistics.

**Labour force or household survey:** Some labour force and other types of household surveys include questions on trade union membership and coverage by a collective agreement. These surveys collect information directly from workers or other members of the household. While this is a preferred source of statistics, the number of countries that request this information is still rather limited.

**Establishment survey:** Surveys of enterprises or establishments collect information on the numbers of workers belonging to a trade union and the numbers of workers covered by collective agreements. While a good source of statistics, these surveys tend to be limited to non-agricultural formal sector establishments and the number of countries with establishment surveys that collect this information is rather small.

The most frequently reported source of information on both trade union membership and collective bargaining coverage was administrative records. The second most important source was a labour force or household survey, and for collective bargaining coverage the establishment surveys. Very few respondents reported data from other sources. For a number of countries the sources of the data is not available.

## Social dialogue indicators and their computation

In order to improve comparability of data, in regions with more homogenous industrial relations frameworks and where similar methodologies are used to collect information, databases have been developed that adjust the denominator to include only those workers eligible to join a trade union or eligible to bargain (e.g. see Visser, in Annex 1). In computing the rates for the 2008-09 inquiry, data has not been adjusted due to a lack of information about non-eligible workers in many countries.

Given that the inquiry included countries at very different levels of development, two different denominators were used in the computations. The first used the number of wage and salaried earners as a denominator and the second, total employment as a denominator. To ensure maximum comparability, labour market information was drawn from the ILO LABORSTA database (<http://laborsta.ilo.org/>). Three rates are reported in Tables 1 and 2. The first rate is a proportion of wage and salaried earners, the second rate is a proportion of total employment and the third is the rate reported by the government, based on their own computations.

Steps were taken to check the consistency of the data. Where computed rates differed from the rate reported by the government, special care was taken to check labour market information being used as the denominator and to validate numerical values reported by countries. The general consistency of the statistics was also checked against the databases contained in Annex 1.

### 3.1 Trade union density rates

For the purpose of this indicator, a trade union is defined as an “independent association of workers, constituted for the purposes of furthering and defending the workers’ interests” – (Art. 10, Freedom of Association and the Right to Organise Convention, 1948 (No. 87)).

The rates in Table 1 are computed as follows:

---

## A. Proportion of wage and salaried earners

This rate expresses the number of trade union members as a proportion of wage and salaried workers. It is calculated using data provided by a Statistical Office or Labour Administration and wage and salaried earners from the ILO's LABORSTA database. Ideally, only trade union members in wage employment are included in the numerator. For these reasons, it is thus important to know the composition of the union (i.e. whether its membership includes unemployed, retired, or self-employed members) and to exclude these from the numerator. However, it is sometimes difficult to estimate which trade union members are wage earners. In these cases the numerator uses total trade union membership. These data are indicated by an asterisk in Table 1.

### Trade union density as a proportion of wage and salaried earners

$$\text{Trade union density} = \frac{\text{union members earning wages}}{\text{wage and salary earners}} \times 100$$

or

$$\text{Trade union density} = \frac{\text{total union members}}{\text{wage and salary earners}} \times 100$$

## B. Proportion of total employment

Since developing economies may have missing data and/or large informal sectors, taking wage and salaried earners as the denominator may not provide a realistic picture of the union density rate. For this reason, we also calculate the number of trade union members as a proportion of all those in employment (whether in the formal or informal economy). This is calculated using data provided by a Statistical Office or Labour Administration and total employment from the ILO's LABORSTA database.

### Trade union density as a proportion of total employment

$$\text{Trade union density} = \frac{\text{union members}}{\text{total employment}} \times 100$$

## C. Reported proportion

This reflects the rate reported by the National Statistics Office or Labour Administration in the surveyed country. It was often difficult to establish the basis on which this rate was calculated since figures of total union membership were not provided.

---

### 3.2 Collective bargaining coverage rate

For the purpose of this indicator, collective bargaining encompasses “*negotiations which take place between an employer, a group of employers or one or more employers’ organizations, [...] and one or more workers’ organizations, [...] for determining working conditions and terms of employment.*” (Article 2, ILO Promotion of Collective Bargaining Convention, 1981 (No. 154)). This should include the determination of remuneration.

The rates in Table 2 for collective bargaining coverage are as follows:

#### A. Proportion of wage and salaried earners

This rate expresses the number of workers covered by collective agreements as a proportion of wage and salaried workers. This is calculated using data provided by a Statistical Office or Labour Administration and wage and salaried earners from the ILO’s LABORSTA database.

##### Collective bargaining coverage as a proportion of wage and salaried earners

$$\text{Collective bargaining coverage} = \frac{\text{workers covered}}{\text{wage and salaried earners}} \times 100$$

#### B. Proportion of total employment

Since developing economies may have large informal sectors, taking wage and salaried earners as the denominator may not provide a realistic picture of the role that collective bargaining plays in labour market governance. For this reason, we also calculate the number of workers covered by collective agreements as a proportion of all those in employment (whether in the formal or informal economy). This is calculated using data provided by a Statistical Office or Labour Administration and total employment from the ILO’s LABORSTA database.

##### Collective bargaining coverage as a proportion of total employment

$$\text{Collective bargaining coverage} = \frac{\text{workers covered}}{\text{total employment}} \times 100$$

#### C. Reported proportion

This reflects the collective bargaining rate reported by the National Statistics Office or Labour Administration in the surveyed country.

---

## 4. Observations

Tables 1 and 2 provide data on trade union density and collective bargaining rates, both computed by the ILO and reported by the National Statistics Office or Labour Administration in the responding country. As noted above, indicators on trade union density or collective bargaining coverage need to be interpreted within a particular industrial relations and labour market context. The ILO has indeed done this as part of a more comprehensive review of trends and developments.<sup>4</sup> However, some observations can be made.

The first concerns the difference between countries at different levels of development. The capacity to collect this data and the quality of the information provided is more limited in developing regions and countries. Where statistics are available, these show that in general, trade union density and collective bargaining coverage in developing countries is significantly lower than that of higher income countries. In developing countries with highly segmented labour markets, there is also a significant difference between trade union density and collective bargaining coverage rates for wage and salaried earners and the rates for total employment (which include own-account and workers in the informal economy). Institutionalized industrial and employment relations do play an important role in some developing countries in determining the terms and conditions of employment in formal, wage employment, however, from these indicators it appears that the role that collective agreements play in regulating the terms and conditions of all those in employment tends to be limited. For example, whereas collective bargaining agreements cover 20.8 per cent of wage and salary earners in Malawi, this only represents 2.7 per cent of all those in employment (see Table 2). Of course these social dialogue indicators should be interpreted with caution, since trade unions may influence labour market policies through their representation on national tripartite social dialogue institutions and many are involved in organizing informal economy workers.

Second, the results of the inquiry confirm evidence to date on the interaction between collective bargaining, administrative regulations and labour law. For example, countries with multi-employer bargaining systems and extension mechanisms have higher collective bargaining coverage rates (Traxler et al, 2001). Indeed in countries such as Austria, Belgium, Denmark, France, Finland, Italy and Portugal, collective bargaining coverage is not only significant, but also substantially higher than the union density rate as a result of multi-employer bargaining and the extension of collective agreements.<sup>5</sup>

---

<sup>4</sup> See ILO, 2009, “Negotiating for Social Justice” and the various country studies available at <http://www.ilo.org/public/english/dialogue/ifpdial/events/tripartitemeeting.htm>

<sup>5</sup> Either through ‘erga omnes’ extension, enlargement or functional equivalents. See <http://www.eurofound.europa.eu/eiro/2002/12/study/tn0212102s.htm>

Third, where data was disaggregated by sex, most countries report more men than women belonging to a trade union and higher coverage of men than of women by collective agreements. Of course, women also make up a smaller share of wage employment in many countries.

## 5. Conclusion

The statistics collected during the 2008-09 inquiry do provide a useful basis for assessing the strength and quality of social dialogue and organized labour relations within a particular country context. However, the inquiry again highlighted the need to develop statistical guidance that can facilitate the comparability of statistical outputs. This needs to emphasise the importance of disaggregating data according to sex.
